1. INTRODUCTION

1.1 Purpose

The purpose of this report is to summarize the quality control results for the confirmation sampling activities conducted for WP-437.

1.2 Scope

This report covers only those quality control samples collected during confirmation sampling activities as directed by the *Confirmation Sampling Plan Details for the Disposal Cell Facility (WP-437)* (Ref. 1) and the *Chemical Plant Area Cleanup Attainment Confirmation Plan* (Ref. 2).

2. DATA EVALUATION

Data evaluation was performed on WP-437 final analytical data to determine whether data quality objectives developed for the Weldon Spring Site Remedial Action Project (WSSRAP) were met and to ensure overall data quality results were generated from these remedial activities. Data evaluation was performed in accordance with the *Project Management Contractor Quality Assurance Program* (QAP) (Ref. 3) and the *Environmental Quality Assurance Project Plan* (Ref. 4). The data evaluation process was completed by data verification, data review, data validation, and data management and reduction activities as stated in the *Chemical Plant Area Cleanup Attainment Confirmation Plan* (Ref. 2).

2.1 Data Verification

Data verification was conducted in accordance to ES&H 4.9.1, *Environmental Monitoring Data Verification*, to ensure that documentation and data were reported in compliance with established reporting requirements and standard operating procedures (SOPs), and to ensure that all analyses were performed. All analytical results received from the laboratory were reviewed to verify samples were properly handled according to WSSRAP protocol. The following factors were reviewed and evaluated: sample identification, chain-of custody, holding times, sample preservation requirements, Sample Analysis Request Forms, data reviews, laboratory tracking, data reporting requirements, and the database transfer.

2.2 Data Review

Data packages were reviewed to ensure the final data were properly identified, analyzed, reported, and met data quality requirements (DQRs). The data were also reviewed to check for inconsistencies with the field quality control (QC) samples. Final analytical results were also compared to the preliminary analytical results to identify any changes in data.

During confirmation of WP-437 areas, soil samples were obtained in accordance with the details provided in the sampling plan (Ref. 1). The plan indicates that quality control samples were to be taken at a frequency of 1 per 20 samples or 5%. The quality control samples collected during this event include duplicates, field replicates, secondary duplicates, matrix spikes/matrix spike duplicates, and equipment blanks.

Table 2-1 provides a summary of QC samples collected during WP-437 confirmation activities. With the exception of those numbers bolded in Table 2-1, the remainder of the QC samples met the 5% frequency requirement for both radiological and chemical samples. The QC analytical data are provided in Appendix A through F.

2.3 Data Validation

Data validation was performed on 10% of all analytical data generated from the WP-437 confirmation sampling activities. Data validation was conducted in accordance with ES&H 4.9.2, *Environmental Monitoring Data Validation.* Only 9 data points associated with WP-437 (RU 15 through RU 25) were rejected during validation.

3. QC SAMPLE RESULTS

3.1 Duplicate/Secondary Duplicate/Field Replicates

Duplicate (DU) samples are aliquots taken from the parent sample at the laboratory. Duplicate samples are collected for radiological and metal parameters (see matrix duplicates in Section 3.2 for organics). Field replicates (FR) and secondary duplicates (SD) are both split in the field from the parent sample. The field replicate is sent to the same laboratory as the parent, while the secondary duplicate is sent to a different laboratory. The FR, SD, and DU results are compared to the parent sample and the relative percent difference (RPD) is calculated for each. The probability of meeting the recommended guidelines for FR and SD is much less due to the non-homogeneity of the sample matrices between sample containers and using separate laboratories. The recommended RPD for radiological and chemical parameters is less than or equal to 50% and 35%, respectively. RPDs are not calculated when one or both of the results are non detects. If one or both of the results are less than five times the detection limit; the RPD value is considered of limited value due to higher tolerance limits near the analytical detection limit and, therefore, no further analysis is required. In those cases where the RPDs are greater than the recommended limit, the data are further evaluated as discussed below.

Average RPDs for the radiological duplicates, field replicates, and secondary duplicates were within the recommended limits. For chemical duplicates, field replicates, and secondary duplicates; average RPDs for metals were within the recommended limits of 35%. Table 3-1 presents a summary of the results.

Organic analyses (2,4,6-TNT, PCBs, PAHs) had numerous FR and SD collected, but very few data were above the detection limit. Organic duplicate data were evaluated and were generally above the 35% limit. However, since very few data points (above detection) were available organics accuracy was evaluated using matrix spike and matrix spike duplicate data in Section 3.2, therefore see Table 3-2 for results.

3.2 Matrix Spike/Matrix Duplicate/Matrix Spike Duplicate

The matrix spike and matrix spike duplicate samples are sample aliquots treated the same as the parent sample, but spiked with a known amount of specified parameters. The samples are then processed along with the parent sample and percent recoveries (REC) are calculated after analysis. These results determine the precision of the method in a given sample matrix. In addition, the RPD between the matrix spike and matrix spike duplicate is calculated to determine the accuracy in a given sample matrix. The matrix spikes are done for all chemical analyses, while the matrix spike duplicates are only required for organics (i.e., PAHs).

The matrix duplicate is processed as the regular sample and the relative percent difference is calculated after analysis. This sample is used to determine the accuracy of the method in a given sample matrix and are not required for organics.

The average percent recoveries for all contaminants were within the acceptable range of 70 – 130 %. The average relative percent differences, calculated for the organics, were also within the recommended limit of 35% or less. Table 3-2 provides a summary of the matrix spike and matrix spike duplicate results.

3.3 Equipment Blanks

Equipment blanks (EB) are used to monitor the effectiveness of the process used to clean equipment prior to or in between sample collection. Table 3-3 presents a summary of the equipment blank results.

With the exception of Thorium-230, equipment blank sample results showed little sign of possible contamination. Approximately 43% of the Thorium-230 equipment blank samples had results greater than five times the detection limit. Initially, these values appear to indicate a potential contamination problem of the sampling equipment, but due to the non-equivalent ratios between water and soil activities, the concentrations of Thorium-230 in the equipment blank

water are actually extremely low. (For example, the highest concentration of Thorium-230 in the equipment blank water was 2.74 pCi/l which equates to 0.00274 pCi/g. This concentration (0.00274 pCi/g) is extremely low and would not be detectable using standard analytical methodology.) Therefore, no sampling equipment decontamination problems for Thorium-230 occurred.
